This research was supported by a grant from the U.S. Social Security Administration (SSA) as part of the Retirement and Disability Research Consortium (RDRC). The findings and conclusions are solely those of the authors and do not represent the views of SSA, any agency of the federal government, or NBER and University of Wisconsin-Madison's Center for Financial Security.

Introduction

The U.S. labor force participation (LFP) rate, which measures the fraction of the population that are either employed or unemployed but actively looking for a job, peaked at 67.3% in early 2000 after increasing for about 40 years. Since then, the LFP rate has been declining for most of this century. In particular, it declined to about 66% by the end of 2004, remained roughly flat for over 2 years until the start of the Great Recession in the second half of 2007, and then declined to 62.4% in September 2015. The LFP rate has remained slightly below 63% in the last two years. A closer look at the LFP rate by age, gender and education reveals that it declined for most of the demographic groups.

The decline in the LFP rate has attracted a lot of attention. Many explanations have been proposed. Some examples are the ageing of the population, the increase in school enrollment among the youth, the increase in the number of individuals with mental and physical health issues, the rise in incarceration and criminal records, the stagnation of real wage for low-skilled workers and the rising wage inequality, and technological changes that may have either reduced the demand for labor (through, for example, the automation of routine tasks and the use of robots).

While each of the proposed explanations may contribute to the recent decline in the LFPR, their relative importance is not well understood. This project attempts to fill this gap. We examine the evolution of LFP rate for different demographic groups to gauge the effect of demographic changes. We estimate the transition rates across different labor market statuses to see whether more workers are leaving the labor force

or fewer workers are entering the labor force. We also use wage data to get a sense of the relative importance of demand and supply factors. Overall, we find that roughly half of the decline in labor force participation is attributable to demographic shifts, but that labor force participation within most demographic groups has been continuously declining. Disability is an increasingly common impediment to work, but wage incentives also play a role, as declines in labor force participation seem to be associated with weakening wage incentives to enter or re-enter the labor force.

The recent decline in the Labor Force Participation (LFP) rate has important implications for both national economic growth and individual well-being. By investigating the factors behind this decline, this project provides useful information regarding the effects of current policies. This project can inform us on what types of policies could potentially be used to raise the LFP rate.
